

# Constraining CP violation in the Higgs–fermion interactions

Henning Bahl

THE UNIVERSITY OF  
**CHICAGO**

Argonne HEP Theory Seminar, December 6<sup>th</sup> 2022

## Talk based on

- **2007.08542, JHEP 11 (2020) 127:**

*Indirect CP probes of the Higgs-top-quark interaction: current LHC constraints and future opportunities;*  
in collaboration with P. Bechtle, S. Heinemeyer, J. Katzy, T. Klingl, K. Peters, M. Saimpert, T. Stefaniak, and G. Weiglein.

- **2110.10177, JHEP 03 (2022) 017:**

*Constraining CP-violation in the Higgs-top-quark interaction using machine-learning-based inference;*  
in collaboration with S. Brass.

- **2202.11753, Eur.Phys.J.C 82 (2022) 7, 604:**

*Constraining the CP structure of Higgs-fermion couplings with a global LHC fit, the electron EDM and baryogenesis;*  
in collaboration with E. Fuchs, S. Heinemeyer, J. Katzy, M. Menen, K. Peters, M. Saimpert, and G. Weiglein.

- **Work in preparation** in collaboration with E. Fuchs, and M. Menen

# Outline of the talk

Global LHC fit

Constraining CP violation using machine learning

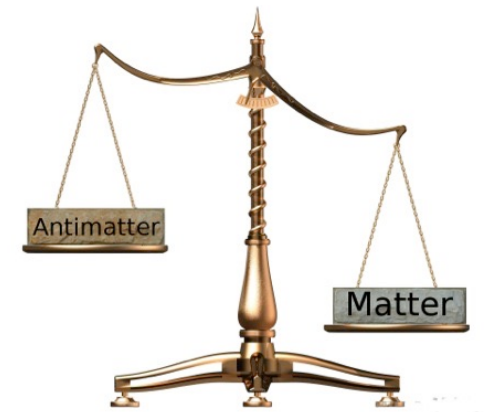

Complementarity with EDM and baryogenesis constraints

# Introduction

*Why should we care about CP violation in the Higgs–fermion couplings?*

# CP violation in the Higgs sector

- New sources of CP violation are necessary to explain the baryon asymmetry of the Universe.
- One possibility: CP violation in the Higgs sector.

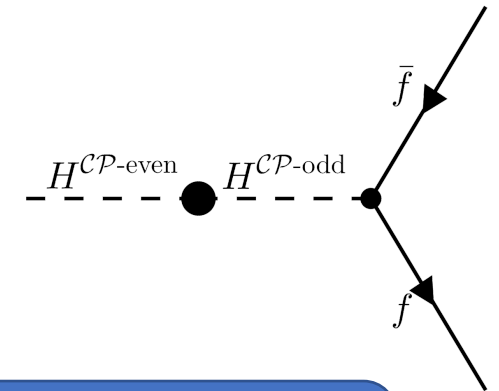

Is the SM-like Higgs boson a CP-admixed state?

- CP violation in the Higgs sector can be constrained by
  - demanding significant contribution to the baryon asymmetry (BAU)
  - electric dipole measurements,
  - collider measurements.

# The CP nature of the Higgs boson

- CP violation in  $HVV$  couplings already tightly constrained via VBF and  $pp \rightarrow VH$  production as well as  $H \rightarrow 4l$  decay. [ATLAS,CMS:...,2002.05315, 2104.12152,2109.13808,2202.06923,2205.05120]
- CP-violating  $HVV$  coupling can only be induced at the loop level  $\rightarrow$  expected to be small in most BSM theories.
- CP violation in Higgs–fermion couplings can be induced at the tree level.

Focus of this talk: Constraining CP violation in the Higgs–fermion interactions.

# Constraining CP violation

CP violation in the Higgs sector can be constrained using:

- **Pure CP-odd observables:**
  - Unambiguous markers for CP violation: e.g.
    - EDM measurements,
    - decay angle in  $H \rightarrow \tau^+ \tau^-$ .
  - Experimentally difficult for some processes (i.e., top-associated Higgs production).

# Constraining CP violation

CP violation in the Higgs sector can be constrained using:

- **Pure CP-even observables:**
  - Many rate measurements are indirectly sensitive: e.g.
    - Higgs production via gluon fusion,
    - $H \rightarrow \gamma\gamma$ .
  - Deviations from SM need not be due to CP violation.

# Constraining CP violation

CP violation in the Higgs sector can be constrained using:

- **Kinematic information:**
  - Effectively mixes CP-even and CP-odd observables.
  - High sensitivity expected since all available information is used.
  - Can be difficult to reinterpret if multivariate analysis is used.

Exploit all three complementary approaches to learn as much as possible!

# Why should we look for CP-violating $Hf\bar{f}$ couplings now?

- More and more experimental CP measurements:
  - $Htt$  coupling:  $t\bar{t}H$ ,  $tH$ ,  $tWH$  production (with  $H \rightarrow \gamma\gamma, \bar{b}b$ ) using kinematic analysis,
  - $H\tau\tau$  coupling:  $H \rightarrow \tau\tau$  using CP-odd observable,
  - $ggH$  coupling:  $H + 2j$  production using CP-odd observable.
- Increased precision on indirectly sensitive channels.
  - E.g.,  $ggH$ ,  $H \rightarrow \gamma\gamma$ , etc.
- Much more luminosity to be collected at HL-LHC.
- Tighter upper bounds on CP violation from EDM measurements.

- Combine LHC measurements in global fit.
- Propose ways to improve measurements in the future.
- Compare LHC measurements with EDM bounds and baryogenesis constraints.

# Effective model

- Modify Yukawa interactions by (e.g. generated by dim-6  $(\phi^\dagger \phi) Q_L \tilde{\phi} t_R$  operator)

$$\mathcal{L}_{\text{yuk}} = - \sum_{f=u,d,c,s,t,b,e,\mu,\tau} \frac{y_f^{\text{SM}}}{\sqrt{2}} \bar{f} (c_f + i\gamma_5 \tilde{c}_f) f H,$$

- Allow moreover for CP-conserving modification of  $HVV$  couplings

$$\mathcal{L}_V = c_V H \left( \frac{M_Z^2}{v} Z_\mu Z^\mu + 2 \frac{M_W^2}{v} W_\mu^+ W^{-\mu} \right)$$

- SM:  $c_f = 1$ ,  $\tilde{c}_f = 0$ ,  $c_V = 1$ .
- Parametrize effect of undiscovered colored and neutral BSM particles via effective Higgs–gluon and Higgs–photon interactions.

# Global LHC fit

*What can we learn from current LHC data?*

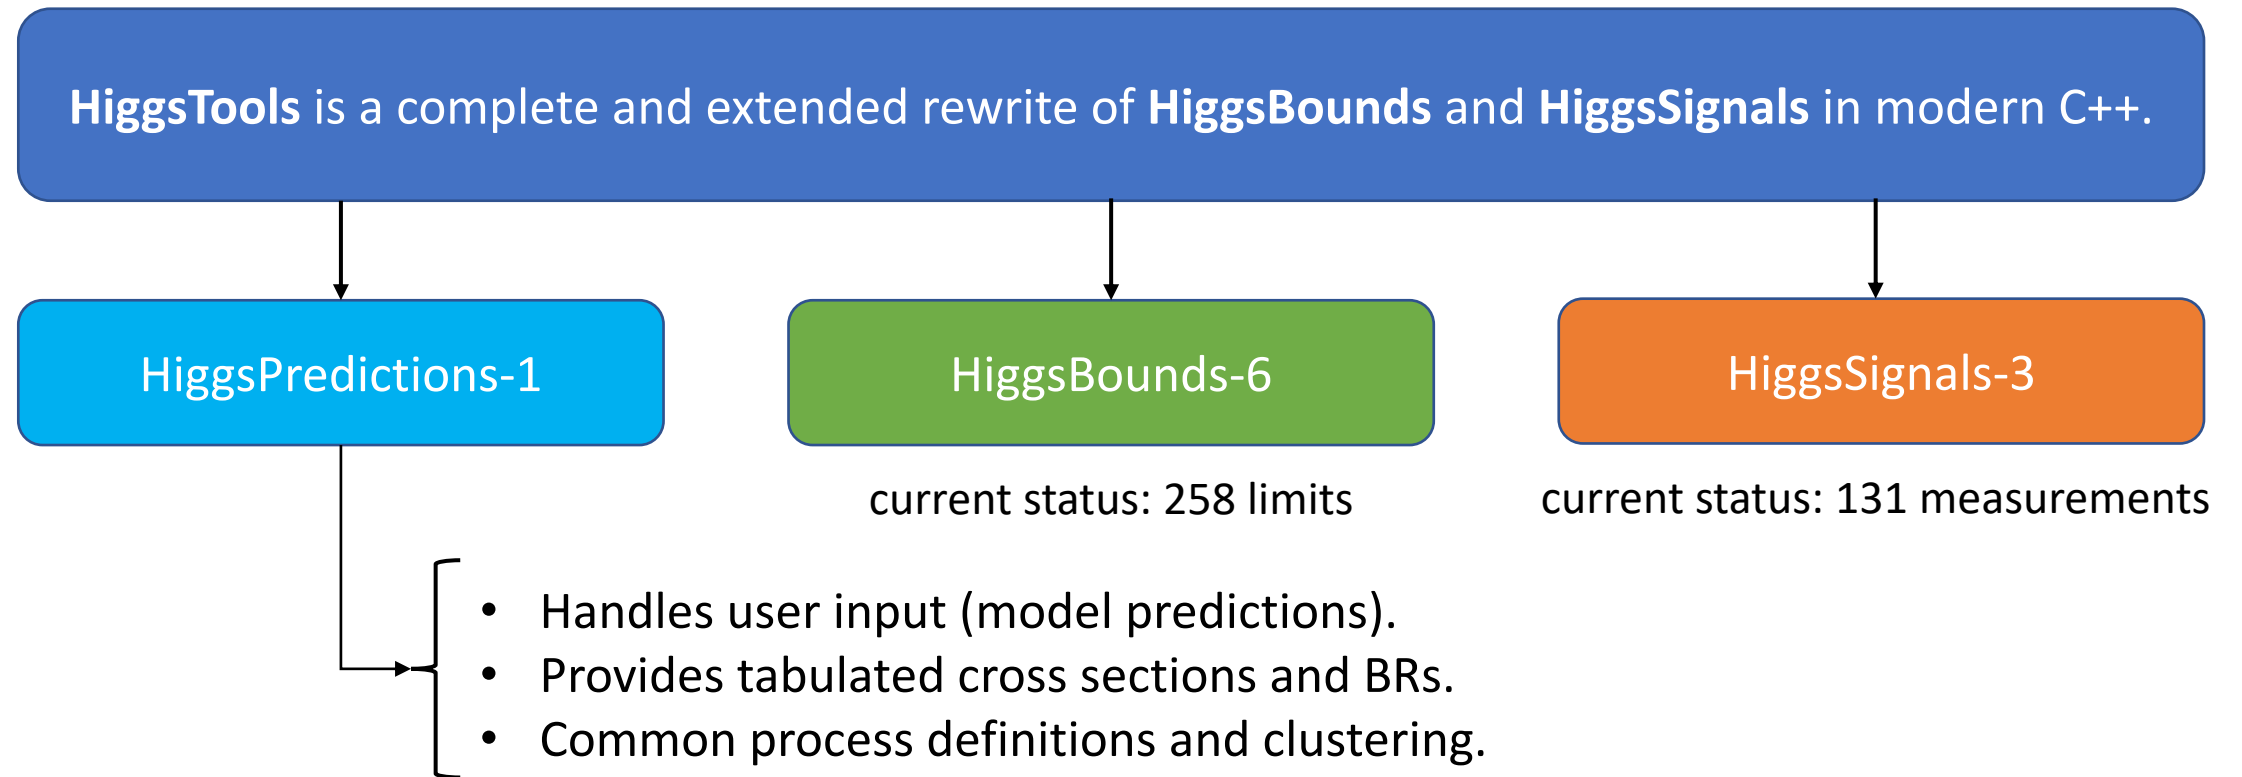

# LHC constraints — setup

- Experimental input:
  - All relevant Higgs measurements:
    - Rate measurements (production + decay),
    - $ZH$  STXS measurements ( $p_T$  shape),
    - CMS  $H \rightarrow \tau\tau$  CP analysis, [2110.04836]
    - did not include dedicated experimental top-Yukawa CP analyses (difficult to reinterpret in another model).
  - If available, included all uncertainty correlations.
- Scanning using either random scan or Markov-chain algorithm,
- $\chi^2$  fit performed using HiggsSignals including  $\sim 100$  different measurements.

# Interlude: HiggsTools

[HB et al., 2210.09332]

➔ C++ interface for high performance; Python and Mathematica interfaces for ease of use.

# Starting point — 1 flavor fits: $\tau$

[HB et al., 2202.11753]

- Without CMS  $H \rightarrow \tau\tau$  CP analysis ring-like structure since  $\Gamma_{H \rightarrow \tau\tau} \propto c_\tau^2 + \tilde{c}_\tau^2$  (similar for muon-Yukawa coupling).
- With CMS  $H \rightarrow \tau\tau$  CP analysis, we can differentiate between CP-even and CP-odd tau-Yukawa coupling.

# 1 flavor fits: $b$

[HB et al., 2202.11753]

- Ring-like structure since  $\Gamma_{H \rightarrow bb} \propto c_b^2 + \tilde{c}_b^2$ .
- Bottom-Yukawa coupling, however, also affects  $ggH$  rate:
  - $\frac{\sigma_{gg \rightarrow H}}{\sigma_{gg \rightarrow H}^{\text{SM}}} \simeq 1.1c_t^2 + 2.6\tilde{c}_t^2 - 0.1c_t c_b + \dots$
- Negative  $c_b$  values disfavored since  $ggH$  rate is enhanced by  $\sim 20\%$ .
- Direct bottom CP measurements very difficult.

Indirect CP constraints will remain important for the bottom-Yukawa coupling.

# Top-Yukawa coupling

- Probe top-Yukawa coupling at the loop-level via  $gg \rightarrow H$ ,  $H \rightarrow \gamma\gamma$ ,  $gg \rightarrow ZH$ :

- $\kappa_g^2 \equiv \frac{\sigma_{gg \rightarrow H}}{\sigma_{gg \rightarrow H}^{\text{SM}}} \simeq \boxed{1.1c_t^2 + 2.6\tilde{c}_t^2} - 0.1c_t c_b - 0.2\tilde{c}_t \tilde{c}_b + \dots$ , disfavors large  $\tilde{c}_t$ .
- $\kappa_\gamma^2 \equiv \frac{\Gamma_{H \rightarrow \gamma\gamma}}{\Gamma_{H \rightarrow \gamma\gamma}^{\text{SM}}} \simeq 1.6c_V^2 \boxed{-0.7c_V c_t} + 0.1c_t^2 + 0.2\tilde{c}_t^2 + \dots$ , disfavors negative/small  $c_t$ .
- $\frac{\sigma_{gg \rightarrow ZH}}{\sigma_{gg \rightarrow ZH}^{\text{SM}}} \simeq 0.5c_t^2 + 0.5\tilde{c}_t^2 + 2.4c_V^2 \boxed{-1.9c_V c_t} \dots$ , disfavors negative  $c_t$ .

# Top-Yukawa coupling

- Probe top-Yukawa coupling at the tree-level via top-associated Higgs production:
  - Three subchannels:  $t\bar{t}H$ ,  $tH$ ,  $tWH$ .
  - Difficult to disentangle experimentally.
  - Consider combined signal strength.

# 1 flavor fits: $t$

[HB et al.,2007.08542]

- $ggH$  and  $H \rightarrow \gamma\gamma$  total rates strongly constraint CP violation in top-Yukawa coupling.
- Relies on assumption that no other BSM physics affect  $ggH$  and  $H \rightarrow \gamma\gamma$ .
- What happens if we allow  $\kappa_\gamma$  and  $\kappa_g$  to float freely?

# 1 flavor fits: $t$ — free $\kappa_\gamma, \kappa_g$

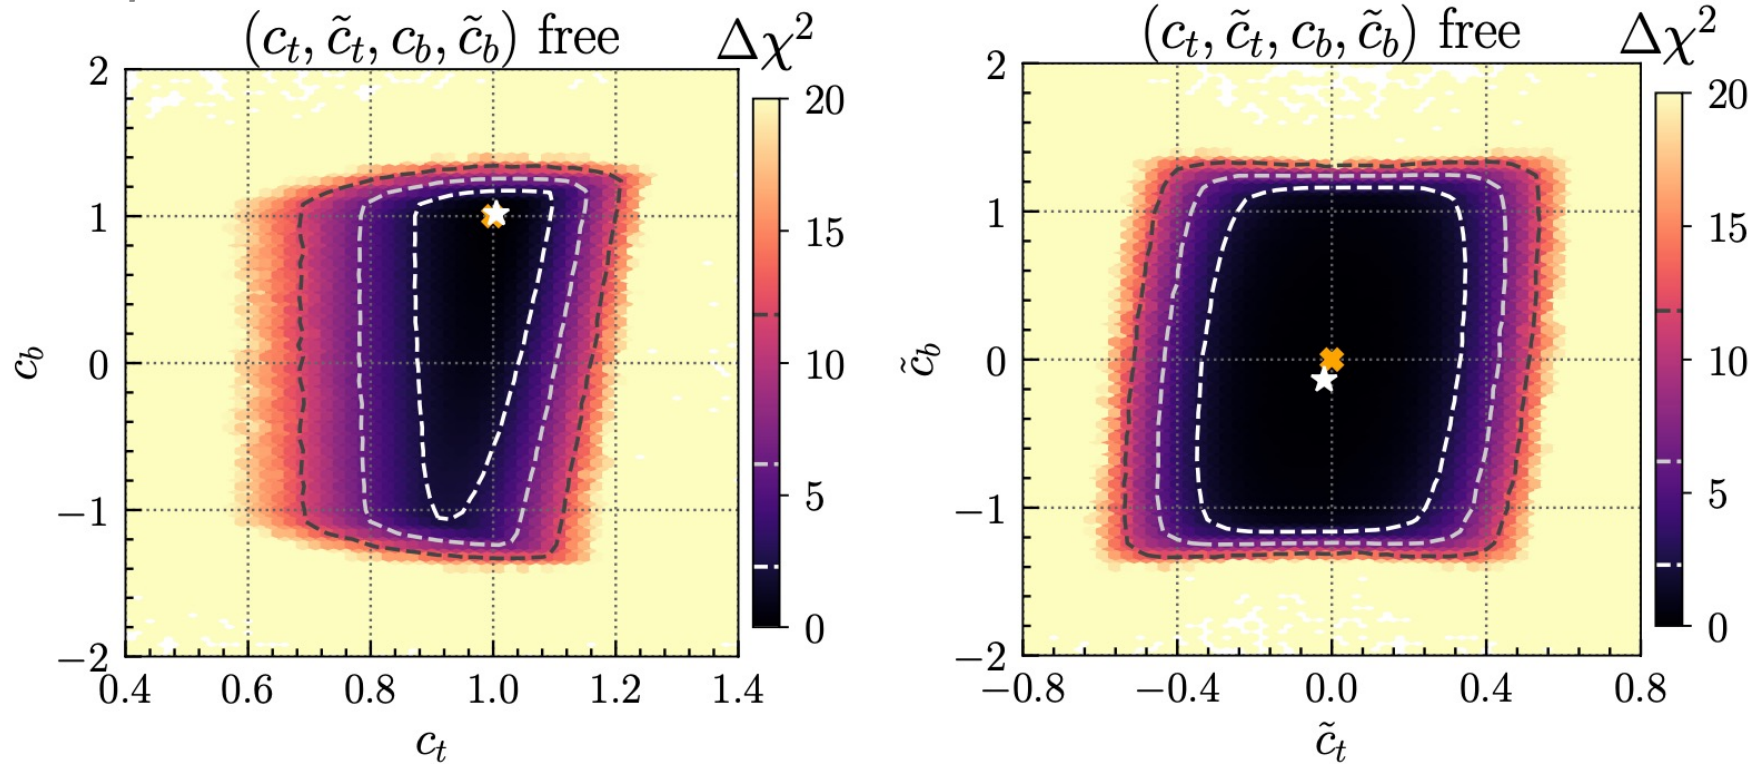

[HB et al., 2007.08542]

- Colored and charged BSM particles can cancel the effect of a modified top-Yukawa coupling.
- Top-associated Higgs production is a more model-independent but weaker probe.

# 2 flavor fits: $t$ and $b$

[HB et al., 2202.11753]

- $ggH$  rate correlates top and bottom Yukawa couplings:  $\kappa_g^2 \simeq 1.1c_t^2 + 2.6\tilde{c}_t^2 - 0.1c_t c_b - 0.2\tilde{c}_t \tilde{c}_b$ .
- Correlation of CP-odd coupling modifiers weaker since bounds on  $\tilde{c}_t$  are stronger.

# Constraining CP-violation using machine learning

*How can we improve the LHC bounds on the top-Yukawa coupling in the future?*

# Future probes of the top-Yukawa interaction

- Future rates measurements:
  - Need to disentangle  $t\bar{t}H$  and  $tH$  to improve sensitivity on  $\tilde{c}_t$ .  
[HB et al., 2007.08542]
  - Possible alternative channels:  $t\bar{t}$ ,  $t\bar{t}t\bar{t}$ .  
[Cao et al.,1901.04567;Martini et al.,2104.04277]
  - Even at HL-LHC comparably weak bounds expected.
- Multivariate analyses exploiting kinematic information:
  - BDT analysis, [CMS,2003.10866;ATLAS,2004.04545]
  - matrix-element approach,[e.g. Goncalves et al,1804.05874;Kraus et al.,1908.09100]
  - High sensitivity expected.
- Future measurements of CP-odd observables:
  - [e.g. Faroughy et al.,1909.00007; Bortolato et al.,2006.13110;Barman et al.,2110.07635]
  - Difficult since top quarks need to be reconstructed.
  - Resulting projected limits are relatively weak.

# Kinematic analysis using ML-based inference I

[Brehmer et al.,1906.01578,1805.12244,1805.00013,1805.00020,1808.00973]

- Allows to extract the full available information (maximal sensitivity).
- No information loss due to binning (as for BDT analysis).
- No approximation of shower and detector effects (as for matrix-element approach).
- Use implementation in public code MadMiner designed to work with MadGraph + Pythia + Delphes.

[Brehmer,Kling,Espejo,Cranmer,1907.10621]

# Kinematic analysis using ML-based inference II

- Focus on top-associated Higgs production ( $t\bar{t}H, tH, tWH$ ) with  $H \rightarrow \gamma\gamma$ .
- We require at least one lepton  $\rightarrow$  consider  $ZH, WH$  as backgrounds.
- Non-Higgs backgrounds are assumed to be subtracted by fit to smoothly falling  $m_{\gamma\gamma}$  distribution.
- Free parameters:  $c_t, \tilde{c}_t$ , and  $c_V$  (+ renormalization scale  $\mu_R$ ).
- Defined 47 observables used by neural network (photon, jet, lepton momenta, Higgs  $p_T$ , etc.).
- Averaged over ensemble of six neural networks to minimize ML uncertainty.

$\Rightarrow$  Evaluate likelihoods for different luminosities at the LHC + HL-LHC.

# Expected limits at the (HL-)LHC

[HB&Brass,2110.10177]

- Can also interpret result in terms of mixing angle  $\tan \alpha = \tilde{c}_t/c_t$ .
- Additional variation of  $c_V$  (and of the renormalization scale) only slightly weakens bounds ( $\sim 5^\circ$  for 300  $\text{fb}^{-1}$ ).

# Using ML to construct CP-odd observables I

[HB, Fuchs, Menen, in preparation, results preliminary]

- **Goal:** probe CP-violating Higgs–gluon interaction via  $H + 2j$  production.

$$\mathcal{L}_{Hgg} = -\frac{1}{4v} H \left( -\frac{\alpha_s}{3\pi} c_g G_{\mu\nu}^a G^{a,\mu\nu} + \frac{\alpha_s}{2\pi} \tilde{c}_g G_{\mu\nu}^a G^{a,\mu\nu} \right) \quad (\text{heavy top limit: } c_g = c_t, \tilde{c}_g = \tilde{c}_t)$$

- The squared amplitude is then decomposed as:

$$|\mathcal{M}_{Hjj}|^2 = c_g^2 |\mathcal{M}_{Hjj}^{\text{CP-even}}|^2 + 2c_g \tilde{c}_g \text{Re}[\mathcal{M}_{Hjj}^{\text{CP-even}} \mathcal{M}_{Hjj}^{\text{CP-odd}*}] + \tilde{c}_g^2 |\mathcal{M}_{Hjj}^{\text{CP-odd}}|^2$$

- Construct CP-odd observables via  $\Delta\Phi_{jj}$ :

Henning Bahl

# Using ML to construct CP-odd observables II

[HB, Fuchs, Menen, in preparation , results preliminary]

- ML approach: train two neural networks
  1. signal–background separation,
  2. interference term ( $c_g \tilde{c}_g$ ) vs. squared terms ( $c_g^2, \tilde{c}_g^2$ ).
- Define CP-odd observables:  $O_{NN} = P_+ - P_-$ .  
[Bhardway et al., 2112.05052]

( $P_{+/-}$ : probability for pos./neg. interference event)

projected limit

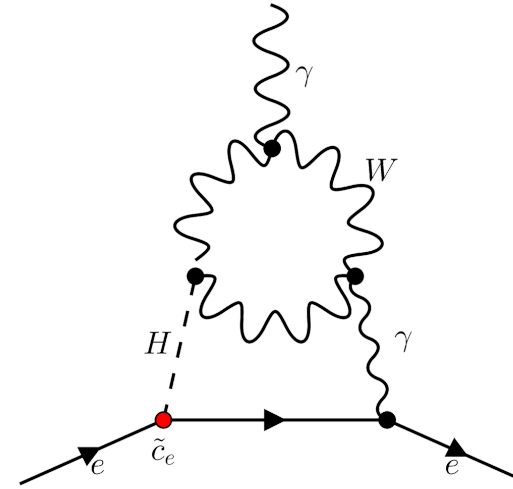

→ Significant improvement in sensitivity when using  $O_{NN}$  instead of  $\Delta\Phi_{jj}$ .

# Complementarity with EDM and baryogenesis constraints

*Can CP violation in the Higgs sector explain the BAU?*

# EDM constraints

- Several EDMs are sensitive to CP violation in the Higgs sector.
- We consider only constraints from theoretically cleanest EDM: the electron EDM.  
[Brod et al.,1310.1385,1503.04830, 1810.12303, 2203.03736;Panico et al.,1810.09413;Altmannshofer et al.,2009.01258]
- Strongest limit by ACME collaboration:  $d_e^{\text{ACME}} = 1.1 \cdot 10^{-29} e \text{ cm}$  at 90% CL. [ACME, *Nature* 562 (2018) 7727, 355-360]
- $\frac{d_e}{d_e^{\text{ACME}}} \simeq c_e (870.0 \tilde{c}_t + 3.9 \tilde{c}_b + 3.4 \tilde{c}_\tau + \dots) + \tilde{c}_e (610.1 c_t + 3.1 c_b + 2.8 c_\tau - 1082.6 c_V + \dots)$
- Bounds strongly depend on assumptions about electron-Yukawa coupling.

# Baryon asymmetry of the Universe

- Different techniques used in the literature to calculate BAU  $Y_B$ :

- Vev-insertion approach (VIA),

[Huet&Nelson,9504427,9506477;Carena et al., 9603420;Riotto, 9712221;Lee et al.,0412354;Postma et al.,2206.01120]

- WKB (or FH) approximation.

[Joecy et al.,9410282;Kainulainen et al.,0105295, 0202177;Prokopec et al., 0312110, 0406140;Konstandin et al.,1302.6713, 1407.3132]

- VIA approach yields consistently higher results by orders of magnitude.
- We use VIA approach with bubble wall parameters close to optimal values for  $Y_B$ :

[de Vries,1811.11104;Fuchs et al.,2003.00099,2007.06940;Shapira,2106.05338]

$$\frac{Y_B}{Y_B^{\text{obs}}} \simeq 28\tilde{c}_t - 0.2\tilde{c}_b - 11\tilde{c}_\tau + \dots$$

$Y_B$  values should be regarded as **upper bound** on what is theoretically achievable.

# 1 flavor results: $t$ and $b$

[HB et al.,2202.11753]

- CP-violating bottom-Yukawa coupling contributes too less to BAU.
- CP-violating top-Yukawa coupling strongly constrained by eEDM → not able produce sufficient BAU.

# 1 flavor results: $\tau$ and $\mu$

[HB et al.,2202.11753]

- CP-violating tau-Yukawa coupling can potentially explain BAU within LHC and eEDM constraints.
- LHC constraints on CP-violating muon-Yukawa coupling are **stronger** than eEDM bounds.

# 2 flavor results: $t$ and $b$

[HB et al.,2202.11753]

Maximal  $Y_B/Y_B^{\text{obs}}$  within LHC and eEDM constraints:

	$t$	$b$	$c$	$\tau$	$\mu$
$t$	0.03				
$b$	0.42	0.05			
$c$	0.37	0.19	0.01		
$\tau$	6.9	6.9	6.9	3.2	
$\mu$	0.18	0.19	0.16	3.2	0.16

- Presence of more than one CP-violating coupling allows for cancellation in eEDM.  
 → Larger values for  $Y_B/Y_B^{\text{obs}}$  can be reached.

# Dependence on electron-Yukawa coupling

[HB et al.,2202.11753]

- Electron Yukawa-coupling only very weakly constrained ( $g_e \leq 268$  at 95% CL).
- If  $c_e$  smaller, eEDM significantly weakened.
- Moreover, we can fine-tune CP-odd electron-Yukawa coupling such that  $d_e < d_e^{\text{ACME}}$ .
- Neutron EDM has similar dependence on first-generation quark-Yukawa couplings.

LHC bounds important since they do not depend on 1<sup>st</sup> gen. Yukawa couplings.

# Conclusions

# Conclusions

*Initial question:* how well can we constrain **CP violation in the Higgs–fermion interactions** and what are the implications for the BAU?

**LHC** already tightly constrains CP violation in the **top- and tau-Yukawa couplings**.

To improve bounds in the **future**, we need to exploit all available information using e.g. **machine-learning** to construct likelihood or CP-odd observables.

**Complementarity of LHC, EDM, and baryogenesis** constraints:

- CP violation in tau-Yukawa coupling remains viable source for electroweak baryogenesis.
- LHC allows to distinguish between CP violation in various Yukawa couplings (beginning to probe 2<sup>nd</sup> generation).
- EDM interpretation strongly depends on first generation Yukawa couplings.

**Thanks for your attention!**

# Appendix

# Reasons for not including ATLAS and CMS top CP studies

- CMS study: [2003.10866]
  - All Higgs production modes (apart from top-associated Higgs production) are constrained to their SM predictions.
  - No two-dimensional likelihood given when our study was published (now available in [CMS-PAS-HIG-19-009])
- ATLAS study: [2004.04545]
  - Two setups:
    1.  $\kappa_g$  (and  $\kappa_\gamma$ ) constrained by other measurements ( $ggH$ ) excluding  $t\bar{t}H$  and  $tH$  but events generated at NLO  $\rightarrow$  top-associated Higgs production and gluon fusion cannot be regarded as independent.
    2.  $\kappa_g$  and  $\kappa_\gamma$  calculated as function of  $c_t$  and  $\tilde{c}_t$ .
  - Assumed  $HVV$  couplings equal to SM value.

# Experimental top CP studies [ATLAS,2004.04545;CMS,2104.12152]

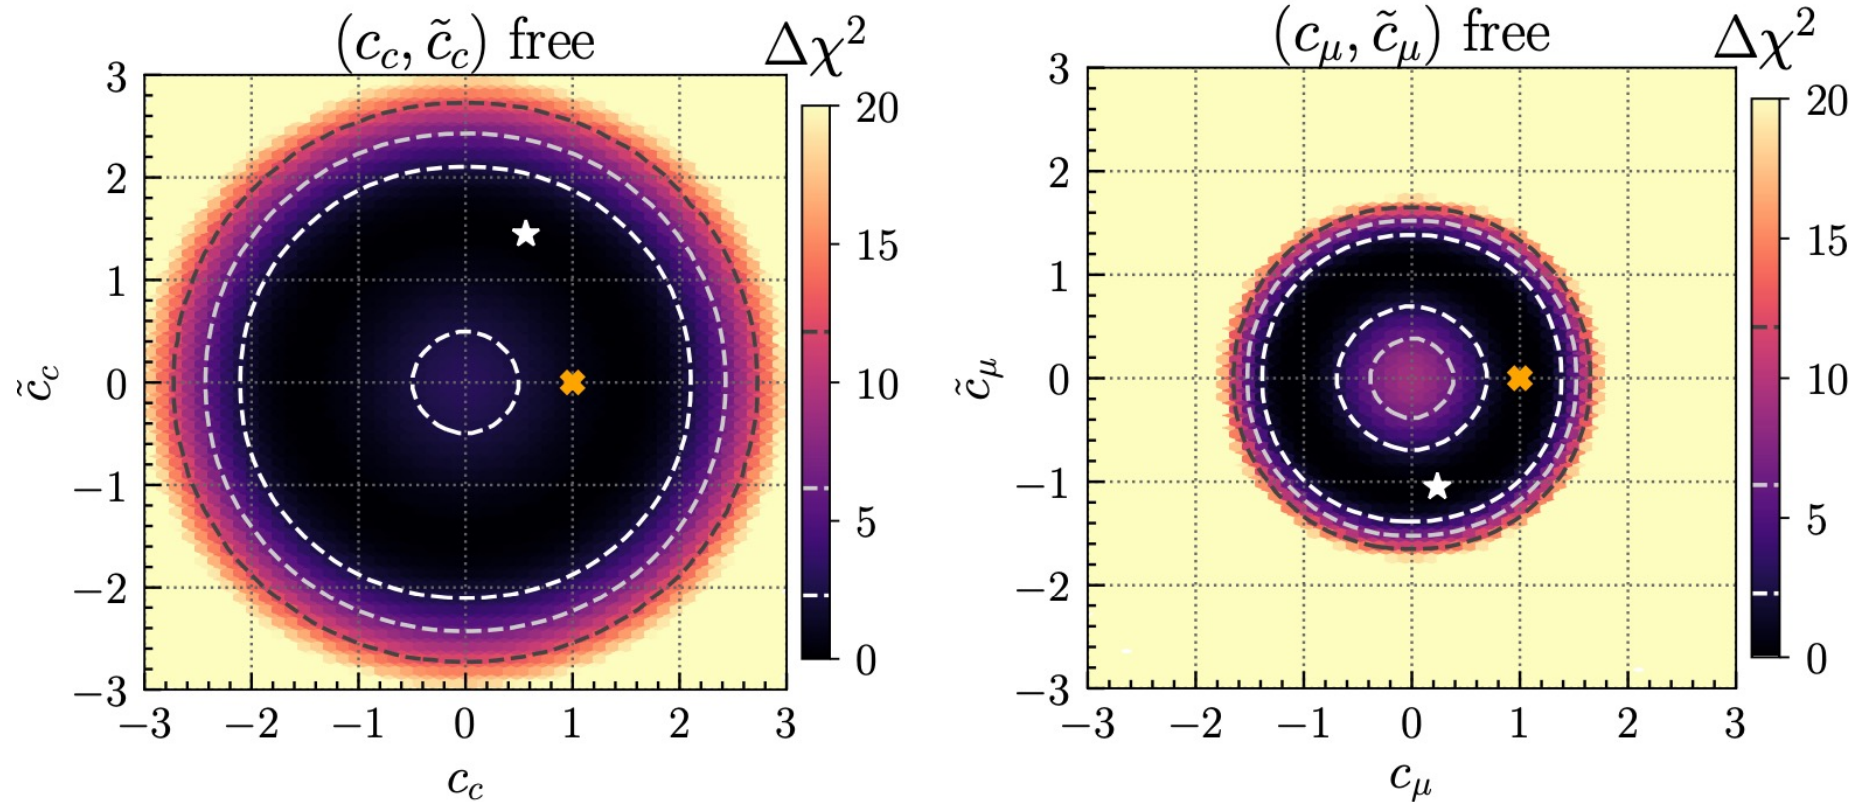

# Correlation between $ggH$ and $t\bar{t}H$ at NLO

[Maltoni,Vryonidou,Zhang,1607.05330]

# Charm- and muon-Yukawa couplings

# Global modification fits

- Universal fermion coupling modifiers:  $c_f = c_t = c_b = \dots = c_\tau$ ,  $\tilde{c}_f = \tilde{c}_t = \tilde{c}_b = \dots = \tilde{c}_\tau$ .
- Dominated by constraints on top-Yukawa coupling.
- Additional varying  $c_V$  reopens negative  $c_f$  range.

observable	condition
$N_\gamma$	$\geq 2$ (with $ \eta  < 2.5$ and $p_T > 25$ GeV)
$(p_{T,1}^\gamma, p_{T,2}^\gamma)$	$\geq (35, 25)$ GeV
$m_{\gamma\gamma}$	$[105 - 160]$ GeV
$(p_{T,1}^\gamma/m_{\gamma\gamma}, p_{T,2}^\gamma/m_{\gamma\gamma})$	$\geq (0.35, 0.25)$
$N_\ell$	$\geq 1$ (with $ \eta  < 2.5$ and $p_T > 15$ GeV)
$m_{\ell\ell}$	$[80, 100]$ GeV vetoed if same flavour
$N_{jet}$	$\geq 1$ (with $ \eta  < 2.5$ and $p_T > 25$ GeV)

**Table 1:** Summary of preselection cuts.

# Interpretation in terms of CP-violating angle

# Variation of $c_V$ and renormalization scale

# Limits in case of deviation from SM

- CP-mix:  $c_t = 1, c_{\tilde{t}} = 0.5, c_V = 1.$

# Which observables drive these constraints?

- Use Fisher matrix to evaluate information for different observables

$$I_{ij}(\theta) = \mathbb{E} \left[ \frac{\partial \log p_{\text{full}}(\{x\}|\theta)}{\partial \theta_i} \frac{\partial \log p_{\text{full}}(\{x\}|\theta)}{\partial \theta_j} \middle| \theta \right], \quad \text{with} \quad \text{cov}(\hat{\theta}|\theta)_{ij} \geq I_{ij}^{-1}(\theta),$$

→ *The higher the information, the more precise we can measure a parameter.*

- E.g., for SM point we have

$$I_{ij}^{\text{full}}(\text{SM}) \simeq \begin{pmatrix} \boxed{91.4} & 13.7 & 0.1 \\ 13.7 & \boxed{108.2} & -0.1 \\ 0.1 & -0.1 & \boxed{0.004} \end{pmatrix},$$

Information about  $c_V$ 
Information about  $c_t$

Correlation of  $c_t$  and  $c_V$ 
Information about  $\tilde{c}_t$

- Evaluate Fisher matrix for various 1D and 2D histograms, full likelihood, XS only, kinematics only.

# Fisher information for SM scenario

[HB&Brass,2110.10177]

Which combinations of couplings  
can we constrain how well?

Total amount of  
capture information

- $\tilde{c}_t$  not constrained by rate.
- Use of kinematic information mandatory.
- No single observable able to capture information about  $\tilde{c}_t$ .

# Fisher information for CP-mixed scenario

- For CP-mixed scenario, Higgs  $p_T$  captures sizeable amount of information on  $c_{\tilde{t}}$ .
- ↓
- $p_T$  binned STXS measurements useful to constrain CP violation in the top-Yukawa coupling.
